

A decorative border of brain activity maps surrounds the central text. The maps are arranged in a grid-like pattern, with some maps appearing in pairs. Each map shows a lateral view of a brain hemisphere with various regions highlighted in different colors (red, yellow, green, blue, purple) to represent different activity patterns. The background of the slide is a dark, textured blue.

Activity patterns in the brain: breaking up the problem into pieces

Extract pieces

- **Skeletonize** each slice of segmented non-white matter (only step in 2-D).
- **Split** the resulting sulcus skeleton into left and right **hemispheres**.
- **2-D** pieces in adjacent slices are grouped to make **3-D** pieces.

Functional mapping tests

The resulting labels may be transferred to a coregistered volume of activity data.

Mindboggle labeled activity from 5 subjects undergoing 4 standard tasks that are known to elicit activity in specific regions (Hirsch, 2000). We determined whether Mindboggle's labels included those regions. According to Mindboggle, of the 45 gyri expected to be activated (9 gyri distributed across 4 tasks performed by 5 subjects), 44 were activated, well within expected variance of the subject pool.

Mindboggle

Evaluation

Label agreement metric:

$$\frac{V_a}{V_c} = \frac{\text{intersection with the same label}}{\text{subject volume}} = \frac{\sum |A_i \cap M_i|}{\sum |M_i|}$$

Evaluation

- A **one-way ANOVA** was performed to test if the means are the same for the label agreements obtained by each of the methods.
- A **multiple comparison test** was then performed to determine which pair of means are significantly different (95% confidence interval around the mean, based on the Studentized range distribution).
- **Mindboggle** obtained a significantly higher mean filled mask label agreement than did linear registration or SPM2 ($p < 0.05$).

Evaluation

- The atlas was used to label an artificially lesioned version of itself.

Conclusions

Mindboggle:

- Fully automated
- Feature-based (vs. intensity-based registration)
- Does not assume that different brains preserve topography
- Robust to reduced and nonuniform image quality
- Competitive with standard techniques
- Performs just as well when parts of brain are removed
- Labels may be transferred to any regions of interest (e.g. structures or activity data)
- Multiple atlases provide independent label sets, confidence measures, higher accuracy
